The brittle-lacquer technique of experimental stress analysis relies on the failure by crack- ing of a layer of a brittle coating which has been applied to the surface under investigation. The coating is normally sprayed onto the surface and allowed to air- or heat-cure to attain its brittle properties.

Unlike the heat transfer case where the gradient is used directly, in stress analysis the multiple components of the displacement gradients are combined into alternate forms called strains. The strains have geometrical interpretations that are summarized in Figure 3-2 for 1D and 2D geometry. In 1D, the normal strain is just the ratio of the change in length over the original length, $\epsilon_x = \partial u / \partial x$.
